TITLE: Mass-spectrometer outfit for studying the distribution of intensity of molecular beam in space

SOURCE: Pribory i tekhnika eksperimenta, no. 3, 1966, 160-162

TOPIC TAGS: mass spectrometer, molecular beam

ABSTRACT: The development is reported of a special outfit consisting of an MI-1301 (Soviet-made) mass spectrometer and a special chamber. The chamber houses a molecular gun with a mechanism for moving it with respect to the ionization space of the spectrometer. The molecules emerging from evaporation cell 1 (see figure) enter ionization box 2 at right angles to electron 3 and ion 4 beams. The driving mechanism is explained. The angular distribution of Mg^{24} particles emerging from a cylindrical effusion crucible is shown, as is the curve of beam-density distribution over the cross-section of the crucible port. The ion-current measurement error is 3% or less. The outfit operates at pressures 0.0001-1 torr in the molecule source. Furnace-temperature stability is $10^{\circ}/hr$ or better within 300-1000°C. Orig. art. has: 5 figures.

TITLE: Effect of palladium on the corrosion resistance of titanium

SOURCE: Zashchita metallov, v. 2, no. 1, 1966, 32-37

TOPIC TAGS: titanium, titanium alloy, corrosion resistance, palladium

ABSTRACT: An investigation was made of the corrosion resistance of non-alloyed Ti and Ti containing 0.01, 0.05, 0.1, 0.2, and 0.5% Pd in HCl (5-30% concentrations at 25°C, 50°C, and at boiling temperature), H₂SO₄ (10-80% concentrations at 25°C, 50°C, and at boiling temperature), and HCOOH (85% concentration at boiling temperature). The results given in the table, showed that there was no lower boundary of Pd concentration below which the passivation of Ti ceased to exist. The necessary concentration of Pd in the Ti-Pd alloy depended on the corrosive activity of the medium. For instance, the addition of ≤ 0.05% Pd increased the corrosion resistance of Ti in an 85% solution of HCOOH at boiling temperature and in ≤ 10% solutions of HCl at temperatures ≤ 50°C. The

Cord 1/2

UDC: 546.319'821'98 : 620.193

L 34423-66

ACC NR: AP6003318

same addition of Pd decreased considerably the corrosion resistance of Ti in more corrosive media. The alloy Ti + 0.2% Pd, which has a sufficiently high resistance to corrosion in all the media investigated except 80% H₂SO₄ solution, should be considered the most universal. The increase of the Pd content to $\leq 0.5\%$, as a rule, had little effect on the corrosion resistance of Ti and evidently is not justified economically. It was found that Pd, added to Ti, decreased the overvoltage of the cathode reaction and displaced the stationary potential of Ti to more positive values. This resulted in an increase in the rate of dissolution in the active region. The larger additions of Pd provided for a transition into the region where Ti is partly or fully passive. The small deceleration of the anodic process observed during the addition of Pd was related to the mechanical effect of a part of the Ti surface. The addition of 0.3% Pd to the alloy OT4, which is widely used in structures, resulted in the formation of an alloy combining elevated mechanical properties with corrosion resistance. Orig. art. has 3 fig. and 1 table.

TITLE: Concerning the coefficient Gamma in the equation for long term strength

SOURCE: Fizika tverdogo tela, v. 7, no. 8, 1965, 2529-2532

TOPIC TAGS: ultimate strength, polymer, polystyrene, polymethylmethacrylate, temperature dependence, structural plastic

ABSTRACT: It is shown that Zhurkov's equation (Vestn. AN SSSR v. 11, 78, 1957) for long-term strength does not apply experimentally to all substances, and that many materials, especially polymethylmethacrylate, polystyrene, and celluloid, as well as all other types of polymer films and fibers differ from it appreciably. This discrepancy between Zhurkov's equation and experimental data is manifest in the fact that the slope of the plot of the long-term strength against the stress is not equal for these substances, and the coefficient γ which enters into this equation is not constant as called for by Zhurkov's theory. In fact, γ is shown to be a decreasing linear function of the temperature. This indicates the importance of a detailed study of the influence of temperature on the coefficient γ of polymer materials, especially those intended for construction purposes. Orig. art. has: 2 figures, 4 formulas, and 1 table.

TITLE: The Dependence of the Angular Correlation in the μ^-e^- -Decay of Energy (Zavisimost' uglovoy korrelyatsii pri μ^-e^- raspade ot energii)

PERIODICAL: Zhurnal Eksperimental'noy i Teoreticheskoy Fiziki, 1958, Vol. 34, Nr 1, pp. 255 - 256 (USSR)

ABSTRACT: At first reference is made to papers dealing with the same subject. The authors investigated the angular correlation in the decay of negative myons in an emulsion. A stack of photo-emulsion layers НИКФИ-Р with a diameter of 10 cm and a thickness of 400 μ was irradiated with a beam of negative myons of the phasotron of the United Institute for Nuclear Research (Ob'yedineniy institut yadernykh issledovaniy). The negative myons were produced in the decay of negative pions with the energy 350 MeV and were then filtered from foreign particles with a carbon-filter. In the emulsion the negative myons were recorded with an energy lying close to the maximum energy. The beam of negative myons could be considered polarized. In the examination of the individual emulsion layers the shut-down of myons with long ranges with decay electrons was observed. Altogether 630 cases of μ^-e^- -decays were

Card 1/3

56-1-51/56

The Dependence of the Angular Correlation in the μ^-e^- -Decay of Energy

utilized. The energy of the electrons was measured by the method of multiple scattering. In order to be able to compare the experimental data with the formula given here, the angle ϑ between the direction of the impulse of the electron emitted in the decay and the spin of the myon must be measured. In 135 cases of μ^-e^- -decays 64 electrons flew forward ($0 < \vartheta \leq 90^\circ$) and 71 electrons flew backward ($90^\circ < \vartheta < 180^\circ$). The spin of the myon is at least in some particles supposed to retain the original direction in the emulsion until the moment of decay. A diagram shows the energy spectra separately for the electrons flying off forward and backward. For the energies $E > 0,6$ the ratio of the electrons "forward-backward" amounts to 25 : 36. At small energies ($E < 0$) 39 particles flew forward and 35 backward. Moreover the asymmetry was investigated in various angular intervals, the "forward-backward" ratios found at energies of > 35 MeV are summarized in a table. Further diagrams compare the energy spectra in different angular intervals with the corresponding theoretical curves. From the analysis of the angular correlation of the μ^-e^- -decay follows a qualitative agreement with the theory of the two-component neutrino. Unfortunately the existing data are not sufficient for quantitative conclusions. There are 2 figures, 1 table, and 4 references, 3 of which are Slavic.

TITLE:

The Depolarization of μ^+ -Mesons in Nuclear Emulsions With
Varying Content of Gelatin (Depolyarizatsiya μ^+ -mezonov v
yadernykh emul'siyakh s razlichnym soderzhaniyem zhelatiny)

PERIODICAL:

Zhurnal eksperimental'noy i teoreticheskoy fiziki, 1958,
Vol 35, Nr 5, pp 1297-1298 (USSR)

ABSTRACT:

The present paper aims at explaining the dependence of the spin depolarization of a positive muon on the relative share of the different components of the emulsion. For this purpose the asymmetry of the distribution of the electrons emitted in the $\mu \rightarrow e$ decay acts (in a forward and rearward direction) is investigated. A chamber composed of layers of the usual NIKFI (type "R") emulsions was irradiated with a positive pion beam of the phasotron of the OIYaI (Joint Institute for Nuclear Research). During investigation of the emulsion, the $\pi^+ \rightarrow \mu^+ \rightarrow e^-$ decays which developed entirely in an emulsion layer, were recorded. Results are given in a table. For the emulsions of all sorts investigated the ratio

Card 1/3

SOV/56-35-5-43/56

The Depolarization of μ^+ -Mesons in Nuclear Emulsions With Varying Content
of Gelatin

$$A = \frac{2(N_{\text{backward}} - N_{\text{forward}})}{N_{\text{backward}} + N_{\text{forward}}} \quad \text{was calculated.}$$

Here N_{backward} , N_{forward} denote the number of electrons emitted in a backward and forward direction respectively. Also after taking all corrections and error sources into account the results obtained indicate a growth of angular asymmetry with an increase of the portion per weight of the gelatin in the nuclear emulsion. At present endeavors are being made to obtain more experimental data for the purpose of fully explaining the character of this dependence. Besides, 1196 cases of $\pi^+ \rightarrow \mu^+ \rightarrow e^+$ -decays were dealt with, which were discovered in a fourfold diluted $(C_2H_4OH)_3N$ -containing emulsion. In this case the asymmetry coefficient is (0.182 ± 0.058) . The authors thank Professor I. I. Gurevich and V. G. Kirillov-Ugryumov for the interest they displayed in this work, and they also express their gratitude to Z. S. Galkina, G. I. Polosina and A. V. Smelyanskaya for their help in investigating the emulsion.

There are 1 figure, 2 tables, and 5 references, 1 of which is Soviet.

TITLE: Investigation of the Depolarization of μ^+ -Mesons in Nuclear Emulsions

PERIODICAL: Zhurnal eksperimental'noy i teoreticheskoy fiziki, 1960,
Vol. 39, No. 6 (12), pp. 1492 - 1496

TEXT: The authors wanted to determine the effect of the relative AgBr-content of a nuclear emulsion upon the asymmetry coefficients for the $\mu^+ - e^+$ decay. An emulsion chamber consisting of free НИКФИ-Р (NIKFI-R) emulsion layers of four different kinds (with different AgBr-content) was exposed to a positive 350-Mev pion beam. The chamber was surrounded by a double iron shield, which attenuated the strength of the scattered field of the accelerator and the terrestrial field to 0,04 oersted. The flux was

$5 \cdot 10^4 / \text{cm}^2$. Work was carried out with ordinary, 2-, 3- and 4-fold diluted NIKFI gelatin emulsion. Concerning the emulsions used, the data of the NIKFI (Scientific Cinematic and Photographic Research Institute), and of the FIAN

Card 1/5

88418

 μ^+ -Mesons in Nuclear Emulsions

S/056/60/039/006/002/063
B006/B056

(Institute of Physics of the AS) are compared with the authors' own data. On the irradiated plates, a total of 45457 $\pi^+ - \mu^+ - e^+$ decay events was recorded, and after evaluation (selection of events with μ^+ -path lengths $> 50\mu$ in the emulsion), 38.192 still remained. The numerical results are given in Table 2. After carrying out the corrections, which are discussed in detail, the asymmetry coefficients for the four degrees of dilution of the emulsions were obtained: $d_{2x1} = 0.100 \pm 0.018$; $d_{2x2} = 0.133 \pm 0.022$
 $d_{2x3} = 0.153 \pm 0.020$ $d_{2x4} = 0.170 \pm 0.022$.

From the data obtained it is possible, by using the formula $P = 3d$, to determine the residual polarization of μ^+ -mesons in AgBr and gelatin separately. For this purpose formula $P = P_1\gamma + P_2(1-\gamma)$ is used, where P_1 and P_2 are the μ^+ -polarization in the decay into gelatin and AgBr, respectively, AgBr, $\gamma = xS/(1+xS)$ is the relative number of μ^+ stopping points in gelatin, x is the volume ratio of gelatin to AgBr, S is the moderating property of the gelatin referred to that of AgBr. S was between 0.34 and unity, and thus one obtained for P_2 a value of between 0.09 and

Card 2/5

88418

Investigation of the Depolarization of
 μ^+ -Mesons in Nuclear EmulsionsS/056/60/039/006/002/063
B006/B056

0.12 and for P_1 of 0.9 - 0.7. An examination of the results obtained by other authors makes a value of $S = 0.8$ appear to be probable. Thus, $P_1 = 0.72 \pm 0.22$ and $P_2 = 0 \pm 0.11$. The strong μ^+ -depolarization in AgBr is discussed from the viewpoint that the latter, apart from multiple electron exchange, is interrelated with the formation of mesonium. The authors finally thank Professor I. I. Gurevich for his advice and interest, Professor V. I. Gol'danskiy and B. A. Nikol'skiy for discussions, and Z. S. Galkin, G. I. Polosin, and A. V. Smelyanskaya for their help in evaluating the emulsions. There are 1 figure, 2 tables, and 20 references: 7 Soviet, 2 Italian, and 10 US.

TITLE: μ^+ -meson depolarization in an electric field

PERIODICAL: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 43,
no. 1(7), 1962, 337-339

TEXT: The authors studied the effect which a strong electric field ($E \sim 10^5$ v/cm) exerts on the depolarization of μ^+ mesons resulting from $\pi-\mu$ decays in photoemulsions. Depolarization of stopped muons is attributed mainly to production of muonium (μ^+e^-); it has, however, also been observed (Swanson, Phys. Rev. 112, 580, 1958) that the "stopped" μ^+ meson precessed in a transverse magnetic field and showed no further depolarization. Thus, muonium must be produced within a very short time immediately after the stoppage. It has not yet been verified by experiment whether the μ^+ meson in condensed matter decays as a free Card 1/2

μ^+ -meson depolarization in an ...

S/056/62/043/001/048/056
B102/B104

particle or after having been captured by a molecule. The authors found out that electrical fields of $E \sim 10^5$ v/cm were able to cause additional depolarization of the stopped muon; which is indicative of a captured muon. Such fields cannot depolarize muons in free or in muonium state. The experiments were made at the synchrocyclotron of the OIYaI with a pulsed 85-Mev π^+ beam (pulse duration 500 μ sec). The muons arising in π - μ decays were stopped in НИКФИ-Р (NIKFI-R) emulsions with increased gelatine content, placed between electrodes. The pulsed field in the emulsion was $1.2 \cdot 10^5$ v/cm (400- μ emulsion layer) and $2.4 \cdot 10^5$ v/cm (200 μ). The additional muon depolarization observed when the field was switched on proves that the stopped muon is captured by a gelatine molecule. There is 1 table.

TITLE: The behavior of a μ^+ -meson in organic substances at low energies

PERIODICAL: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 43,
no. 2(6), 1962, 557-560

TEXT: The inelastic scattering of a muon on the vibrational levels of a hydrogen molecule is investigated. This is done by means of the Ψ function of a triatomic molecule with stationary nuclei; the nuclear coordinates are contained in the Hamiltonian as parameters. The total energy of the system is $E(R_{ab}, R_{ac}, R_{bc}) + T_a + T_b + T_c = \text{const}$, where the indices a and b indicate the proton, c the μ^+ -meson, E is the energy of the triatomic molecule, T is the kinetic energy of the nuclei, and R is the distance between them. In the energy range $0.01 \leq E \leq 1$ one has $\tau_p \ll \tau_0, T_{a,b} \ll T_c$ (2) (τ_p - time of passage of the muon through the molecule, τ_0 - characteristic time of the H_2 oscillations). The inter-

Card 1/3

B104/3108

The behavior of a...

action potential is therefore $V = E_{\text{tot}} + T_c = E(R_{ab}, R_{bc}, R_{ac})$. By means of

$\rightarrow \infty$

the theory of sudden perturbations one obtains: $C_k = \int_{-\infty}^{\infty} V_{10}(t) dt$ (where

$|C_k| \ll 1$) for the amplitude of the transition probability of the molecule to another vibrational level. $V_{10} = (F_a - F_b)a_0/\sqrt{2}$ is derived for the interaction potential, so that $C_1 = a_0(\Delta p_a - \Delta p_b)/\sqrt{2}$ (4) is the amplitude of the transition probability to the first level. a_0 is the oscillation amplitude of the (harmonic) oscillator, F_a and F_b are the projections on the molecule axes of the forces acting on the protons when a muon passes, Δp is the projection of momentum. The probability amplitude can be obtained in this form also by the classical theory, provided that the conditions (2) are fulfilled. Conclusions: the particles are slowed down in a high-molecular substance mainly by the molecular oscillations (inelastic processes). The slowing-down power of a medium can be estimated

The behavior of α ...

from (4). The inelastic scattering cross section is $\sigma = \pi Q^2 x_0^2 p^2 / 3 \cdot 2$.
A possible charge exchange of the μ^+ -meson in the molecule is also pointed out. It is shown that in molecular hydrogen not all muons exchange their charge. All μ^+ -mesons decay in organic substances.

TITLE: Alloy for brazing refractory materials. Class 49, No. 186837

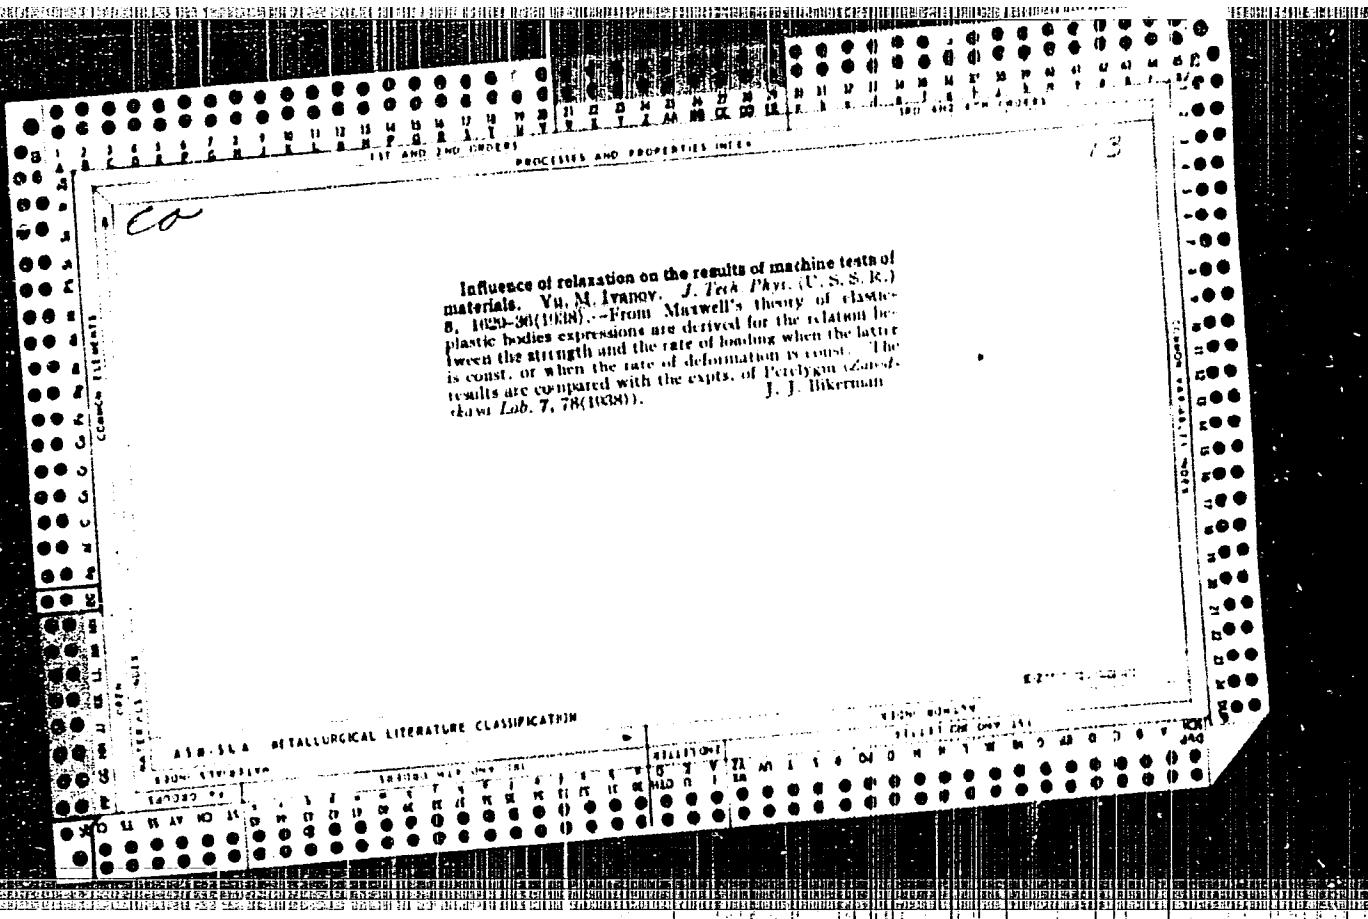

SOURCE: Izobreteniya, promyshlennyye obraztsy, tovarnyye znaki, no. 19, 1966, 124

TOPIC TAGS: refractory metal, ~~refractory metal~~, ~~refractory metal~~, metal brazing, brazing
alloyABSTRACT: This Author Certificate introduces a niobium-base brazing alloy, containing
titanium and vanadium, for refractory materials. To improve the quality of a brazed
joint, the composition of the alloy is set as follows: 20% vanadium, 10—20% titanium
and the balance niobium.

Changes in the microscopic structure of wood during deformation and rupture. Yu. M. Ivanov, T. N. Lomakina, A. N. Lebedev, V. G. Kostylev. Izdat. Akad. Nauk S.S.R. 1961, No. 118.—(see also the microscopic structure of plant wood [18, 23, and 25] in summerwood) during compression at various angles to the grain were studied. During compression of wood until failure ends at 10° to the grain, there is no change in extracellular structure up to the limit of plastic flow and it is assumed that the latter is a function of changes in the tubular or spiral structure. Radial compression perpendicular to the grain results in distortion and flattening of the sclerified tracheids, giving a stable form with symmetrical sides of displaced tracheids, dense packing of the cell walls, and almost complete closure of the lumen. Details of the testing equipment, procedure, and results, and a no. of micrographs of wood sections under compression are given. I. K.

✓ The buckling rupture of wood under compression due to the grain. Yu. M. Ivanov. *Tsudy Ind. Lesn. Akad. Nauk S.S.R.* # 115-20(1973).—Compression failure in various samples of birch, beech, and pine wood was observed. The oblique direction of buckling on tangential faces of rectangular prisms (with the lateral faces parallel to the tangential or radial plane) under compression is believed, due to the resistance of the tangential cell wall to rupture across the grain, and not to the oblique arrangement of the rays containing resin ducts. Apparently failure around the rays, with the appearance of cold blisters, is a secondary phenomenon. John Lake Reith

AUTHORS: Grodzovskiy, G. L., Ivanov, Yu. N., and Tokarev, V. V.

TITLE: Motion of a body with variable mass and constant power consumption in a gravitational field

PERIODICAL: Doklady Akademii nauk SSSR, v. 137, no. 5, 1961, 1082-1085

TEXT: The present paper gives a study of the general case of the optimization of the reactive motion of a body with variable mass in a gravitational field of two centers when the power consumption is constant. For a given trajectory, the acceleration is equal to $a(t) = -\nabla m/m dt$, where V is the escape velocity. The utilizable reactive power may be written as $N = -dmV^2/2dt$. Thus, $a^2/2N = -dm/m^2 dt$. This gives by integration the

weight of the body as a function of time: $G = G_0 \left(1 + \int_0^T \frac{G_0}{2Ng} a^2 dt \right)$. The specific weight of the power source is defined as: $\alpha = G_0/N$, and the

Card 1/7

21968

S/020/61/137/005/011/026
B104/E214

Motion of a body with variable ...

relative total weight initially is given by $\bar{G} = (G_M + G_N)/G_0$

$$= \alpha \left| N/G_0 + 1 - 1 - 1 \right| \left(1 + \int_0^T \frac{G_0}{2Ng} a^2 dt \right). \text{ For a given } a(t) \text{ the quantity } \bar{G}$$

has a minimum: $\bar{G}_{\min} = 2\sqrt{\Phi} - \Phi$ at $(G_N/G_0)_{\text{opt}} = (\alpha N/G_0)_{\text{opt}} = \sqrt{\Phi} - \Phi$,

$$\text{where } \Phi = \frac{\alpha}{2g} \int_0^T a^2 dt. \text{ In the case of a step by step decrease of power}$$

related to a decrease in weight, the maximum relative utilizable weight may be calculated from the formula

$$\bar{G}_{n, \max} = (1 + \Phi_1 - 2\sqrt{\Phi_1}) \prod_{i=1}^n \left(\frac{1 - \Phi_i}{1 + \Phi_i} \right)^2. \quad (4).$$

(4).

Here, $\sum \Phi_i = \Phi$ is given. The optimum ratio between the Φ_i may be

Card 2/7

Motion of a body with variable ...

S/020/61/137/005/011/004
B104/3214

obtained from (4) by differentiation. Fig. 1 graphically shows \bar{G}_{\min} and G_N/G_0 as functions of ϕ . As is seen from this graph, a minimum of \bar{G} requires a minimum of the integral $\int_0^T a^2 dt$. As an illustration, the motion in a plane spiral is studied in the case of small accelerations.

The result obtained is: $x/u_0 = 1/\left(1 - \int_0^T k(t)dt / \frac{R_0}{v_0}\right)^{1/2}$. The next topic

studied is the optimum displacement of a body of variable mass in the time T between two given points. This problem leads to a variation problem for

the integral $I = \int_0^T a^2(t)dt$. Here, the plane motion in the gravitational field of two centers is investigated, one of which is at rest and the other

Card 3/7

Motion of a body with variable ...

S/020/61/137/005/011/026
B104/B214

moves with constant angular velocity ω on a circle of radius r_0 about this center. In order to study the motion of the body in a region in which one of the two centers has a dominating effect on the motion of the body, it is convenient to place the reference system in this center. On these assumptions, the integral of the variation problem introduced above yields the integral

$$I = \int_0^T \left\{ [\ddot{r}_I - r_I(\dot{\psi}_I + \omega)^2 + \frac{k_I}{r_I^2} - \mathfrak{M}_I]^2 + [r_I \ddot{\psi}_I + 2\dot{r}_I(\dot{\psi}_I + \omega) \Psi_I]^2 \right\} dt. \quad (9)$$

Euler's equations of this variation problem are:

$$\dot{a}_{r_I} = \frac{1}{v_{r_I}} \left[\frac{a_{r_I}^2 + a_{\psi_I}^2}{2} + a_{r_I} \left(\frac{v_{\psi_I}^2}{r_I} - \frac{k_I}{r_I^2} \right) - \lambda_I - v_I \frac{v_{\psi_I}}{r_I} \right], \quad (10)$$

$$\dot{a}_{\psi_I} = \frac{1}{r_I} (a_{\psi_I} v_{r_I} - 2a_{r_I} v_{\psi_I} + v_I); \quad (11)$$

$$\dot{v}_I = a_{\psi_I} \Psi_I \dot{\psi}_I + a_{r_I} \mathfrak{M}_I \dot{\psi}_I; \quad (12)$$

$$\lambda_I = -v_{r_I} \left(a_{\psi_I} \Psi_I \dot{\psi}_I + a_{r_I} \mathfrak{M}_I \dot{\psi}_I + \frac{\Psi_I}{r_I} a_{\psi_I} \right) - v_I \frac{\Psi_I}{r_I} - \dot{a}_{r_I} \mathfrak{M}_I - \frac{v_{\psi_I}}{r_I} (v_I - 2a_{r_I} \Psi_I);$$

Card 4/7

S/020/61/137/005/011/026
B104/B214

Motion of a body with variable ...

$$v_r = \dot{r}, \quad v_{\phi} = r(\dot{\psi} + \omega). \quad (14)$$

The problem is simplified and limited to the following variation problem:
It is desired to find a trajectory which gives a minimum for

$\int_{r_1}^{r_2} a^2 dr/v_r$ under the additional isoperimetric condition. The time for
the displacement from r_1 to r_2 ($T = \int_{r_1}^{r_2} dr/v_r$) and the polar angle of
the displacement $\Delta\psi = \int_{r_1}^{r_2} v_\phi dr/rdr$ are given. With their help, expressions

Card 5/7

21968
S/020/61/137/005/011/026
B104/B214

Motion of a body with variable ...

can be found for \dot{a}_r and \dot{a} which agree with (10) and (11) for $\alpha = 2n$, and $\alpha_2 = 2v$. It is shown that in the case of the free fall along the optimum trajectory the acceleration varies linearly with time. Finally, the singularities of the system are also studied. TITLE: The mechanics of space flight with low thrust. I.

SOURCE: Inzhenernyy zhurnal, v. 3, no. 3, 1963, 590-615

TOPIC TAGS: space flight, solar sail, low thrust, rocket thrust,
space ship, space flight mechanics, low thrust rocket, low thrust
vehicle

ABSTRACT: This article is the first in a series of review articles
dealing with the mechanics of space flight at low thrust. On the
basis of Soviet and non-Soviet sources the article reviews these
principal subject areas: 1) the mechanics of space flight with a
solar-sail space vessel, including fundamental relationships and
problems and the flight of such a vessel between planetary orbits
and its escape from a gravitational field; and 2) the mechanics of
space flight with low-thrust engines,² including the selection of
optimum weight ratios for simpler cases of motion and an ideal

TITLE: Motion of a variable mass body with limited power and given active time

SOURCE: Prikl. matem. i mekhan., v. 27, no. 5, 1963, 854-863

TOPIC TAGS: variable mass body, limited power, active time, optimal running time, variational problem, plane parallel gravitational field, limiting case, Mayer problem

ABSTRACT: Several authors have studied optimal working conditions for motion of a variable mass body with limited power of the reactive jet, for optimal running time of the engines. The author generalizes these results by proposing a general method for solving the variational problem with given active time which is less than optimal. He formulates the variational problem for the case in the title and illustrates the general results by analyzing optimal motion in a plane-parallel gravitational field. He investigates two limiting cases for regulating a propulsion system: an ideally regulatable system (variable optimal thrust) and a nonregulatable system (constant thrust). Orig. art. has: 5 figures and 40 formulas.

TITLE: Optimal coupling of propulsion systems

SOURCE: AN SSSR. Izvestiya. Mekhanika i mashinostroyeniye, no. 2, 1964, 9-18

TOPIC TAGS: propulsion, jet propulsion, rocketry, rocket thrust calculation, two stage rocket, rocket motor, jet engine, low thrust rocket motor, rocket motor airborne regulation, stage firing pattern, gas discharge rate

ABSTRACT: Mathematical solutions are presented for variational problems on the optimal coupling of arbitrary propulsion systems, as well as controlled thrust engines in tandem with engines characterized by a controlled rate of escape flow. The weight of the latter is assumed to be proportional to maximum generated thrust, that of the former to peak power or to the sum of two terms, one being proportional to maximum power and the other to maximum thrust. Parallel and succession firing patterns are discussed for engines which can or cannot be regulated in flight. The variational problems are reduced to boundary problems for common differential equations and can be solved as Cauchy's problems with selection of inadequate initial magnitudes. TITLE: Optimum trajectories and parameters of space vehicles with limited-power engines

SOURCE: Kosmicheskiye issledovaniya, v. 2, no. 3, 1964, 414-432

TOPIC TAGS: optimum trajectory, interplanetary trajectory, vehicle weight parameter

ABSTRACT: A plane problem of the round-trip flight of a cosmic vehicle from the gravitational field of the earth to that of another planet is discussed. This problem of transportation of a maximum load (in variational formulation) consists of determining the optimum trajectories and optimum control of the acceleration vector due to thrust, and of the selection of the optimum weight parameters of vehicle components. The trajectory of such a flight consists of the following sections: 1) acceleration and take-off from an orbit around the earth in the terrestrial gravitational field; 2) flight

Card 1/2

ACCESSION NR: AP4041565

in the central field of the sun; 3) deceleration in the gravitational field of the planet and entering some orbit around it; 4) acceleration and take-off from that orbit; 5) return flight; and 6) deceleration and entering some orbit around the earth. The results of the calculation of optimum trajectories of the flight to an external planet (Mars) and internal planet (Venus) are given, as well as the data on the optimum acceleration and deceleration sections of the trajectories, and on the negligible effect of the gravitational fields of planets during flight between their orbits. For the sake of simplicity it is assumed that the orbits of planets are circular and coplanar. Orig. art. has: 17 figures, 5 tables, and 40 formulas.

TITLE: Method of steepest descent applied to determining interorbital trajectories with limited-power engines

SOURCE: Kosmicheskiye issledovaniya, v. 2, no. 3, 1964, 439-440

TOPIC TAGS: space trajectory, steepest descent method, interorbital trajectory, limited power engine, optimum round trip flight

ABSTRACT: Two methods are discussed for solving the variational plane-flight problem of a space vehicle equipped with a limited-power engine between coplanar circular orbits in a central gravitational field: 1) Ritz's method, with determination of the coefficients by the steepest-descent method; and 2) the method of functional steepest descent. The selection of optimum flight trajectories and optimum regimes of operation of an ideal engine of limited power is reduced to the determination of the minimum extremals of the functional

$$J = \int a dt,$$

Card 1/2

ACCESSION NR: AP4041566

where a is the acceleration due to reactive thrust and T is the time of motion. The character of the convergence of the functional J in both methods of solution is shown in diagrams, and the much shorter time of calculation on electronic digital computers by the second method is pointed out. The conditions for optimum round-trip flight (with return on the initial orbit) for cases of "symmetrical" and "asymmetrical" return flights are also examined. Orig. art. has: 9 figures and 12 formulas.

TITLE: Mechanics of low thrust cosmic flights. 3.

SOURCE: Inzhenernyy zhurnal, v. 4, no. 1, 1964, 168-196

TOPIC TAGS: cosmic flight optimization, power-limited vehicle, exhaust velocity, thrust vector, maximum payload, flight trajectory

ABSTRACT: The third and last series in the analysis of cosmic flight optimization of power-limited vehicles has been presented. Part One dealt with the limits of the regulating characteristics of the vehicle system. The attainable variation range for flow rate q and exhaust velocity V is investigated as a function of maximum jet thrust power N_{\max} . The optimum control of the thrust vector, V and N are discussed under the conditions

$$0 < N(t) \leq N_{\max}(V) \leq N_0$$

$$0 < V_{\min} \leq V(t) \leq V_{\max} < \infty$$

Card 1/3

ACCESSION NR: AP4026965

An expression is derived relating the power source weight G_x to the flight trajectory characteristics. In Part Two the motion of a power-limited vehicle is discussed for the case of engine operation time less than the vehicle flight duration. The variational problem is considered under variable thrust power flow rate and thrust vector conditions with the optimum combination of power-limited and exhaust velocity-limited engines. It is shown that this combination yields an advantage in total payload if each type of engine has the same payload before combination. Part Four deals with reliability in engine performance for missions of long duration. The optimization criterion assumed here is the condition of a minimum in the sum of average necessary and reserve fuel weights plus the dead weight of the engine. An example is given where it is shown that in a round trip mission the departure leg takes place faster than the return leg of the trip, shifting the given engine-time break to the beginning of the trajectory. The optimization studies are extended to include weights in addition to the previously considered weights of working substance, power source, and payload. Finally, mid-course correction possibilities are studied, including corrections in velocity and position, and a general expression is derived for the optimal correction moment distribution. Orig. art. has: 145 equations, 11 figures, and 1 table.

TITLE: Additional weight components in problems of optimizing motion with limited power

SOURCE: Prikladnaya matematika i mekhanika, v. 28, no. 1, 1964, 166-170

TOPIC TAGS: weight component, optimal motion, limited power, payload, power source, working mass, engine weight, jet stream, variational problem

ABSTRACT: In most work on optimal motion with limited power it is assumed that the system consists of three weight components: payload, weight of power source, and weight of fuel. More detailed analysis requires the inclusion of additional weight components in the weight formula. The author makes a qualitative study of the properties of optimal control, considering the weight of the engine and the weight of the working mass for the power source. The controlling functions are chosen to be optimal in the sense of guaranteeing maximum payload for fixed initial weight, given initial and final points in the phase space, and fixed time

TITLE: Stepwise approximation of optimal controls

SOURCE: Prikladnaya matematika i mekhanika, v. 28, no. 3, 1964, 528-533

TOPIC TAGS: stepwise approximation, optimal control, optimal position, optimal motion

ABSTRACT: The author is concerned with finding a simple optimal control law. By simple, he means a control law which consists of changing the positions of a regulator a finite number of times. He finds an algorithm for choosing optimal positions and optimal moments for switching positions and he gives examples dealing with optimal motion of a variable mass body with constant use of power. The problem of best approximation of a complicated law by a simple one is studied, i.e., replacing a complicated continuous controlling function by a piecewise-constant one with a given number of levels. Then, instead of an infinite number of positions, there is a given number whose interchange is done at optimal moments of time. Orig. art. has: 30 formulas and 2 figures.

TITLE: Optimum precession of the plane of a circular orbit by a transverse force

12.114

SOURCE: Kosmicheskiye issledovaniya, v. 3, no. 5, 1965, 687-693

TOPIC TAGS: artificial satellite orbit, circular orbit, vehicle engine, propulsion thrust, variational problem, Hamilton equation, linear differential equation

ABSTRACT: This paper is devoted to determining the optimum laws for thrust action in the maneuver of turning the plane of a circular orbit. The case of small angles is examined, and linear equations are then studied and solved analytically. Variational problems are formulated for ideal engines and uncontrollable engines. The differential equations of motion and boundary conditions describing the dynamic maneuver are:

$$\begin{aligned} r &= v, & \dot{v} &= \alpha e + R(r, t), \\ r(0) &= r_0, & v(0) &= v_0, \\ r(T) &= r_1, & v(T) &= v_1. \end{aligned}$$

for an ideal engine of limited power. Differential equations describing the maneuver in question are derived: $\chi = \alpha e \sin(t - \Omega_1)$, $\omega = \alpha e \cos(t - \Omega_1)$,

$$\begin{aligned} \chi(0) &= 0, & \omega(0) &= 0, \\ \chi(T) &= 0, & \omega(T) &= i_1. \end{aligned}$$

The variational problems for the two types of engines are formulated under the assumption that the modulus of reactive acceleration "a" reaches a maximum when crossing the nodal line, and that the control functional J_1 is not a function of the position of the nodal line. For an arbitrary angle Ω_1 that differs from Ω_1^* , the laws of $e(t)$ and $\delta(t)$:

$$\text{I. for } -T_u/4s \leq \Omega_1 \leq T_u/4s$$

$$e = +1, \quad \delta = 1 \text{ when } 0 \leq t \leq t_1, \quad t_1 = \Omega_1 + T_u/4s,$$

$$e = -1, \quad \delta = 1 \text{ when } t_2 \leq t \leq t_1 + \pi, \quad t_2 = \pi + \Omega_1 - T_u/4s,$$

$$e = +1, \quad \delta = 1 \text{ when } t_2 + \pi \leq t \leq t_1 + 2\pi,$$

$$e = (-1)^{m-1}, \quad \delta = 1 \text{ when } t_2 + (m-2)\pi \leq t \leq t_1 + (m-1)\pi,$$

$$\text{II. for } T_u'/4s \leq \Omega_1 \leq \pi - T_u/4s$$

$$e = +1, \quad \delta = 1 \text{ when } t_1 \leq t \leq t_2, \quad t_1 = \Omega_1 - T_u/4s,$$

$$e = -1, \quad \delta = 1 \text{ when } t_1 + \pi \leq t \leq t_2 + \pi, \quad t_2 = \Omega_1 + T_u/4s,$$

$$e = +1, \quad \delta = 1 \text{ when } t_1 + 2\pi \leq t \leq t_2 + 2\pi, \quad (3.21)$$

$$e = (-1)^{m-1}, \quad \delta = 1 \text{ when } t_1 + (m-1)\pi \leq t \leq t_1 + (m-1)\pi,$$

The authors thank D. Ye. Okhotsimskiy for valuable advice and attention. Orig. art. has: 43 formulas.
